I can access the database and work with it via the web interface and the ArcGIS REST API. I have also created a shapefile that I want to access via the web interface but in such a way as not to require the database to be connected. My idea is to access the shapefile on the server and use the Python library arcpy. To do so I can use the arcpy.env.workspace = "" However I don't know how to connect to that shapefile and extract the features. My current code looks like this: import arcpy arcpy.env.workspace = "" shapefile = [my_shapefile_location] feature_class = [my_features] for fc in feature_class: f = [fc] arcpy.SelectLayerByAttribute_management(shapefile, "NEW_SELECTION", f) arcpy.SelectLayerByAttribute_management(shapefile, "SUBSET_SELECTION", f) My goal is to extract the Geometry Field of the feature I just created. A: If you would like to extract the geometry field then you could use the arcpy.da.SearchCursor() function. You will need to store the cursor into a variable and then extract the geometry field in the loop. import arcpy shapefile = "" feature_class = "" with arcpy.da.SearchCursor(shapefile, ["SHAPE@"]) c6a93da74d
